• Homework 1

• Lab 0
  - Due this Thursday

• GitHub classroom (for Lab1-4)
  - Link in Piazza post
  - First member creates the team, other members join the team
  - Don’t forget to fill out Google form
Recap: Architecture Support for OS

• **Manipulating privileged machine state**
  - Dual-mode operation, protected instructions
  - Memory protection: MMU, virtual address

• **Generating and handling “events”**
  - Interrupt, syscall, trap
  - Interrupt controller, IVT
  - Fix vs. notify proceed

<table>
<thead>
<tr>
<th>Exceptions (sync)</th>

• **Mechanisms to handle concurrency**
  - Interrupts, atomic instructions
Today’s topics are processes and process management

- What are the units of execution?
- How are those units of execution represented in the OS?
- How is work scheduled in the CPU?
- What are the possible execution states of a process?
- How does a process move from one state to another?
The Process

• The process is the OS abstraction for execution
  - It is the unit of execution
  - It is the unit of scheduling
  - It is the dynamic execution context of a program
  - Sometimes also called a job or a task

• A process is a program in execution
  - It defines the sequential, instruction-at-a-time execution of a program
  - Programs are static entities with the potential for execution
Processes

- Modern OSes run multiple processes simultaneously
Processes

• Modern OSes run multiple processes simultaneously

• Examples (can all run simultaneously):
  - gcc file_A.c – compiler running on file A
  - gcc file_B.c – compiler running on file B
  - vim – text editor
  - firefox – web browser

• Non-examples (implemented as one process):
  - Multiple firefox windows or vim buffers (still one process)

• Why processes?
  - Simplicity of programming
  - Speed: Higher throughput, lower latency
Speed

• **Multiple processes can increase CPU utilization**
  - Overlap one process’s computation with another’s wait

  ![Diagram](vim -> wait for input -> wait for input -> gcc)

• **Multiple processes can reduce latency**
  - Running A then B requires 100 sec for B to complete
  - Running A and B concurrently makes B finish faster

  ![Diagram](A -> 80s -> B -> 20s)

  - A is slower than if it had whole machine to itself, but still < 100 sec unless both A and B completely CPU-bound
Processes in the Real World

• Processes and parallelism have been a fact of life
  - much longer than OSes have been around…
  - e.g., say takes 1 worker 10 months to make 1 widget
  - Company may hire 100 workers to make 100 widgets
  - Latency for first widget ≪ 1/10 month
  - Throughput may be <10 widgets per month (if can’t perfectly parallelize task)

• You will see these effects in you Pintos project group
  - May block waiting for partner to complete task
  - Takes time to coordinate/explain/understand one another’s code
  - Labs won’t take 1/3 time with three people
  - But you will graduate faster than if you took only 1 class at a time
A Process’s View of the World

- Each process has own view of machine
  - Its own address space
  - Its own open files
  - Its own virtual CPU (through preemptive multitasking)

- \*(char \*)0xc000 different in P1 & P2

- Simplifies programming model
  - gcc does not care that firefox is running

- Sometimes want interaction between processes
  - Simplest is through files: vim edits file, gcc compiles it
  - More complicated: Shell/command, Window manager/app.
Kernel’s View of Processes
Process Components

• A process contains all state for a program in execution
  - An address space
  - The code for the executing program
  - The data for the executing program
  - An execution stack encapsulating the state of procedure calls
  - The program counter (PC) indicating the next instruction
  - A set of general-purpose registers with current values
  - A set of operating system resources
    • Open files, network connections, etc.

• A process is named using its process ID (PID)
Unix PIDs

```bash
$ top - 20:42:55 up 14 days, 15:45, 14 users, load average: 1.27, 0.35, 0.12
Tasks: 145 total, 2 running, 141 sleeping, 2 stopped, 0 zombie
%Cpu(s): 5.6 us, 55.3 sy, 0.0 ni, 0.0 id, 35.6 wa, 0.0 hi, 0.0 si, 3.5 st
Kib Mem: 1016140 total, 7228 free, 858408 used, 85444 buff/cache
Kib Swap: 0 total, 0 free, 0 used. 12892 avail Mem

CS 318 – Lecture 3 – Processes

14
Implementing Process

- Keep a data structure for each process
  - Process Control Block (PCB)
  - contains all of the info about a process

- Tracks state of the process
  - Running, ready (runnable), waiting, etc.

- Includes information necessary to run
  - Registers, virtual memory mappings, etc.
  - Open files (including memory mapped files)
  - PCB is also maintained when the process is not running
    - needed to restore the hardware to the same configuration it was in when the process was switched out

- Various other data about the process
  - Credentials (user/group ID), signal mask, priority, accounting, etc.
  - It is a heavyweight abstraction
struct proc (Solaris)

/*
 * One structure allocated per active process. It contains all
 * data needed about the process while the process may be swapped
 * out. Other per-process data (user.h) is also inside the proc structure.
 * Lightweight-process data (lwp.h) and the kernel stack may be swapped out.
 */
typedef struct proc {
    /*
       Fields requiring no explicit locking
       */

A process has an **execution state** to indicate what it is doing

- **Running**: Executing instructions on the CPU
  - It is the process that has control of the CPU
  - How many processes can be in the running state simultaneously?
- **Ready**: Waiting to be assigned to the CPU
  - Ready to execute, but another process is executing on the CPU
- **Waiting**: Waiting for an event, e.g., I/O completion
  - It cannot make progress until event is signaled (disk completes)

As a process executes, it moves from state to state

- Unix “ps”: STAT/S column indicates execution state
- What state do you think a process is in most of the time?
- How many processes can a system support?
Process State Graph

- **New** → **Ready** via **Create Process**
- **Ready** → **I/O Done**
- **Ready** → **Waiting** via **Unschedule Process**
- **Waiting** → **Schedule Process**
- **Waiting** → **Running** via **I/O, Page Fault, etc.**
- **Running** → **I/O, Page Fault, etc.**
- **Running** → **Terminated** via **Process Exit**
- **Terminated**
State Queues

• How does the OS keep track of processes?
  - The OS maintains a collection of queues that represent the state of all processes in the system
  - Typically, the OS has one queue for each state
    • Ready, waiting, etc.
  - Each PCB is queued on a state queue according to its current state
  - As a process changes state, its PCB is unlinked from one queue and linked into another
State Queues

There may be many wait queues, one for each type of wait (disk, console, timer, network, etc.)
Scheduling

• **Which process should kernel run?**
  - if 0 runnable, run idle loop (or halt CPU), if 1 runnable, run it
  - if >1 runnable, must make scheduling decision

• **Scan process table for first runnable?**
  - Expensive. Weird priorities (small pids do better)
  - Divide into runnable and blocked processes

• **FIFO?**
  - Put threads on back of list, pull them from front:
  - Pintos does this—see ready_list in thread.c

• **Next class discusses in detail**
Preemption

- When to trigger a process scheduling decision?
  - Yield control of CPU
    - Voluntarily, e.g., `sched_yield`
    - system call, page fault, illegal instruction, etc.
  - Preemption

- Periodic timer interrupt
  - If running process used up quantum, schedule another

- Device interrupt
  - Disk request completed, or packet arrived on network
  - Previously waiting process becomes runnable

- Changing running process is called a context switch
  - CPU hardware state is changed from one to another
  - This can happen 100 or 1000 times a second!
Context Switch

- Process $P_0$
  - Executing
  - Interrupt or system call
  - Save state into PCB$_0$
  - ... (omitted)
  - Reload state from PCB$_1$

- Operating system

- Process $P_1$
  - Idle
  - Executing
  - Interrupt or system call
  - Save state into PCB$_1$
  - ... (omitted)
  - Reload state from PCB$_0$

- Idle
Context Switch Details

• Very machine dependent. Typical things include:
  - Save program counter and integer registers (always)
  - Save floating point or other special registers
  - Save condition codes
  - Change virtual address translations

• Non-negligible cost
  - Save/restore floating point registers expensive
    • Optimization: only save if process used floating point
  - May require flushing TLB (memory translation hardware)
    • HW Optimization 1: don’t flush kernel’s own data from TLB
    • HW Optimization 2: use tag to avoid flushing any data

• Usually causes more cache misses (switch working sets)
User’s (Programmer’s) View of Processes
Creating a Process

• **A process is created by another process**
  - Parent is creator, child is created (Unix: ps “PPID” field)
  - What creates the first process (Unix: init (PID 0 or 1))?  

• **Parent defines resources and privileges for its children**
  - Unix: Process User ID is inherited – children of your shell execute with your privileges  

• **After creating a child**
  - the parent may either wait for it to finish its task or continue in parallel
The system call on Windows for creating a process is called, surprisingly enough, CreateProcess:

```c
BOOL CreateProcess(char *prog, char *args) (simplified)
```

- Creates and initializes a new PCB
- Creates and initializes a new address space
- Loads the program specified by “prog” into the address space
- Copies “args” into memory allocated in address space
- Initializes the saved hardware context to start execution at main (or wherever specified in the file)
- Places the PCB on the ready queue
CreateProcess function

Creates a new process and its primary thread. The new process runs in the security context of the calling process.

If the calling process is impersonating another user, the new process uses the token for the calling process, not the impersonation token. To run the new process in the security context of the user represented by the impersonation token, use the CreateProcessAsUser or CreateProcessWithLogonW function.

Syntax

```c++
BOOL WINAPI CreateProcess(
    _In_opt_     LPCSTR                         lpApplicationName,
    _Inout_opt_  LPTSTR                         lpCommandLine,
    _In_opt_     LPSecurity_ATTRIBUTES         lpProcessAttributes,
    _In_opt_     LPSecurity_ATTRIBUTES         lpThreadAttributes,
    _In_         BOOL                           bInheritHandles,
    _In_         DWORD                          dwCreationFlags,
    _In_opt_     LPVOID                         lpEnvironment,
    _In_opt_     LPTSTR                         lpCurrentDirectory,
    _In_         LPSSTARTUPINFO                lpStartupInfo,
    _Out_        LPPROCESS_INFORMATION        lpProcessInformation
);
```
In Unix, processes are created using `fork()`

```c
int fork();
```

- `fork()` creates and initializes a new PCB
- Creates a new address space
- Initializes the address space with a copy of the entire contents of the address space of the parent
- Initializes the kernel resources to point to the resources used by parent (e.g., open files)
- Places the PCB on the ready queue

Fork returns **twice**

- Huh?
- Returns the child’s PID to the parent, “0” to the child
NAME
fork -- create a new process

SYNOPSIS
#include <unistd.h>

pid_t
fork(void);

DESCRIPTION
fork() causes creation of a new process. The new process (child process) is an exact copy of the calling process (parent process) except for the following:

* The child process has a unique process ID.

* The child process has a different parent process ID (i.e., the process ID of the parent process).

* The child process has its own copy of the parent's descriptors. These descriptors reference the same underlying objects, so that, for instance, file pointers in file objects are shared between the child and the parent, so that an lseek(2) on a descriptor in the child process can affect a subsequent read or write by the parent. This descriptor copying is also used by the shell to establish standard input and output for newly created processes as well as to set up pipes.

* The child processes resource utilizations are set to 0; see setrlimit(2).

RETURN VALUES
Upon successful completion, fork() returns a value of 0 to the child process and returns the process ID of the child process to the parent process. Otherwise, a value of -1 is returned to the parent process, no child process is created, and the global variable errno is set to indicate the error.

ERRORS
fork() will fail and no child process will be created if:

[EAGAIN] The system-imposed limit on the total number of processes under execution would be exceeded. This limit is configuration-dependent.

[EAGAIN] The system-imposed limit MAXUSRRC (<sys/param.h>) on the total number of processes under execution by a single user would be exceeded.
What does this program print?
$ gcc -o fork fork.c

$ ./fork

My child is 486

Child of ./fork is 486
Duplicating Address Spaces

```c
child_pid = fork();
if (child_pid == 0) {
    printf("child");
} else {
    printf("parent");
}
```

Parent

```c
child_pid = 486
```

Child

```c
child_pid = 0
```

PC

9/12/17 CS 318 – Lecture 3 – Processes
Divergence

```
child_pid = fork();
if (child_pid == 0) {
    printf("child");
} else {
    printf("parent");
}
```

```
child_pid = fork();
if (child_pid == 0) {
    printf("child");
} else {
    printf("parent");
}
```
$ gcc -o fork fork.c

$ ./fork

My child is 486

Child of ./fork is 486

$ ./fork

Child of ./fork is 498

My child is 498

Why is the output in a different order?
Wait a second. How do we actually start a new program?

```c
int exec(char *prog, char *argv[])
int execve(const char *filename, char *const argv[], char *const envp[])
```

- **exec( )**
  - Stops the current process
  - Loads the program “prog” into the process’ address space
  - Initializes hardware context and args for the new program
  - Places the PCB onto the ready queue
  - Note: It **does not** create a new process

What does it mean for `exec` to return?

Warning: Pintos `exec` more like combined fork/exec
minish.c (simplified)

```c
pid_t pid; char **av;
void doexec () {
    execvp (av[0], av);
    perror (av[0]);
    exit (1);
}
/* ... main loop: */
for (;;) {
    parse_next_line_of_input (&av, stdin);
    switch (pid = fork ()) {
    case -1:
        perror ("fork"); break;
    case 0:
        doexec ();
    default:
        waitpid (pid, NULL, 0); break;
    }
}
```
Why `fork()`?

- **Most calls to `fork` followed by `exec`**
  - could also combine into one `spawn` system call

- **Very useful when the child...**
  - Is cooperating with the parent
  - Relies upon the parent’s data to accomplish its task

- **Example: Web server**

```c
while (1) {
    int sock = accept();
    if ((child_pid = fork()) == 0) {
        Handle client request
    } else {
        Close socket
    }
}
```
Why `fork()`?

- **Most calls to `fork` followed by `exec`**
  - could also combine into one `spawn` system call

- **Very useful when the child...**
  - Is cooperating with the parent
  - Relies upon the parent’s data to accomplish its task

- **Example: Web server**

- **Real win is simplicity of interface**
  - Tons of things you might want to do to child: manipulate file descriptors, set environment variables, reduce privileges, ...
  - Yet `fork` requires no arguments at all
redirsh.c  (Manipulating file descriptors)

Example: command < input > output 2> errlog

```c
void doexec (void) {
  int fd;
  if (infile) { /* non-NULL for "command < infile" */
    if ((fd = open (infile, O_RDONLY)) < 0) {
      perror (infile);
      exit (1);
    }
    if (fd != 0) {
      dup2 (fd, 0);
      close (fd);
    }
  }
  /* ... do same for outfile→fd 1, errfile→fd 2 ... */
  execvp (av[0], av);
  perror (av[0]);
  exit (1);
}
```

Spawning a Process Without fork

• Without fork, needs tons of different options for new process
  - Example: Windows CreateProcess system call
    • Also CreateProcessAsUser, CreateProcessWithLogonW, CreateProcessWithTokenW, ...

```c
BOOL WINAPI CreateProcess(
    _In_opt_ LPCTSTR lpApplicationName,
    _Inout_opt_ LPTSTR lpCommandLine,
    _In_opt_ LPSECURITY_ATTRIBUTES lpProcessAttributes,
    _In_opt_ LPSECURITY_ATTRIBUTES lpThreadAttributes,
    _In_ BOOL bInheritHandles,
    _In_ DWORD dwCreationFlags,
    _In_opt_ LPVOID lpEnvironment,
    _In_opt_ LPCTSTR lpCurrentDirectory,
    _In_ LPSTARTUPINFO lpStartupInfo,
    _Out_ LPPROCESS_INFORMATION lpProcessInformation
);
```
• Why Windows use `CreateProcess` while Unix uses `fork/exec`?

• What happens if you run “exec csh” in your shell?

• What happens if you run “exec ls” in your shell? Try it.

• `fork()` can return an error. Why might this happen?
Process Termination

• All good processes must come to an end. But how?
  - Unix: `exit(int status)`, Windows: `ExitProcess(int status)`

• Essentially, free resources and terminate
  - Terminate all threads (next lecture)
  - Close open files, network connections
  - Allocated memory (and VM pages out on disk)
  - Remove PCB from kernel data structures, delete

• Note that a process does not need to clean up itself
  - Why does the OS have to do it?
wait() a second...

• Often it is convenient to pause until a child process has finished
  - Think of executing commands in a shell

• Unix `wait(int *wstatus)` (Windows: `WaitForSingleObject`)
  - Suspends the current process until any child process ends
  - `waitpid()` suspends until the specified child process ends

• Wait has a return value...what is it?

• Unix: Every process must be “reaped” by a parent
  - What happens if a parent process exits before a child?
  - What do you think a “zombie” process is?
Process Summary

• What are the units of execution?
  - Processes

• How are those units of execution represented?
  - Process Control Blocks (PCBs)

• How is work scheduled in the CPU?
  - Process states, process queues, context switches

• What are the possible execution states of a process?
  - Running, ready, waiting

• How does a process move from one state to another?
  - Scheduling, I/O, creation, termination

• How are processes created?
  - CreateProcess (NT), fork/exec (Unix)
