

Dual Fitting: Algorithm doesn't use LP, analysis constructs dual solution + bounds gap to ALG

Primal-Dual: Algorithm simultaneously builds primal and dual solutions.

Set Cover:

Input: - universe  $U$   
 -  $\mathcal{S} \subseteq 2^U$   
 -  $c: \mathcal{S} \rightarrow \mathbb{R}^+$

Feasible:  $\mathcal{I} \subseteq \mathcal{S}$  s.t.  $\bigcup_{S \in \mathcal{I}} S = U$

Objective:  $\min \sum_{S \in \mathcal{I}} c(S)$

LP (Primal):

$$\min \sum_{S \in \mathcal{S}} c(S) x_S$$

$$\text{s.t.} \quad \sum_{S \in \mathcal{S} : e \in S} x_S \geq 1 \quad \forall e \in U$$

$$x_S \geq 0 \quad \forall S \in \mathcal{S}$$

Dual: Variable  $y_e \forall e \in U$ , constraint for each  $S \in \mathcal{S}$

$$\max \sum_{e \in U} y_e$$

$$\text{s.t.} \quad \sum_{e \in S} y_e \leq c(S) \quad \forall S \in \mathcal{S}$$

$$y_e \geq 0 \quad \forall e \in U$$

## Dual fitting: Greedy

- Init  $U' = U, I = \emptyset$

- While  $U' \neq \emptyset$ :

- Let  $S = \operatorname{argmin}_{T \in \mathcal{S}} \frac{c(T)}{|T \cap U'|}$

-  $I = I \cup \{S\}$

-  $U' = U' \setminus S$

- return  $I$

Notation: At iteration  $t$ , greedy chooses  $S_t$ , which covers  $n_t$  uncovered elements.

Sp.  $e \in U$  first covered in iteration  $t$ .

$\Rightarrow$  Set  $y_e' = \frac{c(S_t)}{n_t}$  (split cost of  $S_t$  among newly covered elements)

$\Rightarrow$  Set  $y_e = \frac{y_e'}{H_n}$  ( $H_n = 1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n}$ )

Lemma:  $y$  is feasible for dual

Assuming lemma:

Thm: Greedy is an  $H_n$ -approximation

PF: Let  $I^*$  optimal solution,  $x_S^* = \begin{cases} 1 & \text{if } S \in I^* \\ 0 & \text{otherwise} \end{cases}$

$$\Rightarrow c(\text{greedy}) = \sum_{S \in I} c(S)$$

$$= \sum_{e \in U} y_e \quad (\text{def of } y_e)$$

$$= H_n \sum_{e \in U} y_e \quad (\text{def of } y_e)$$

$$\leq H_n \sum_{S \in \mathcal{S}} c(S) x_S^* \quad (\text{weak duality: feasible dual} \leq \text{feasible primal})$$

$$= H_n \cdot \text{OPT}$$

PF that  $y$  is dual feasible:

Let  $S \in \mathcal{S}$ . Want to show that  $\sum_{e \in S} y_e \leq c(S)$   
(dual constraint)

-  $a_k = \#$  elements of  $S$  uncovered at beginning of iteration  $k$

-  $A_k \subseteq S$  elements of  $S$  covered in iteration  $k$

$$\Rightarrow |A_k| = a_k - a_{k+1}$$

Greedy alg picks set minimizing "average cost"

$\Rightarrow$  could pick  $S$ , average cost  $\frac{c(S)}{a_k}$

$$\Rightarrow y_e' \leq \frac{c(S)}{a_k} \quad \forall e \in A_k$$

Let  $l = \#$  iterations

$$\begin{aligned} \Rightarrow \sum_{e \in S} y_e &= \frac{1}{H_n} \sum_{e \in S} y_e' \\ &= \frac{1}{H_n} \sum_{k=1}^l \sum_{e \in A_k} y_e' \\ &\leq \frac{1}{H_n} \sum_{k=1}^l \sum_{e \in A_k} \frac{c(S)}{a_k} \\ &= \frac{1}{H_n} \sum_{k=1}^l |A_k| \frac{c(S)}{a_k} \\ &= \frac{1}{H_n} \sum_{k=1}^l (a_k - a_{k+1}) \frac{c(S)}{a_k} \\ &= \frac{c(S)}{H_n} \sum_{k=1}^l \frac{a_k - a_{k+1}}{a_k} \\ &\leq \frac{c(S)}{H_n} \sum_{i=1}^l \frac{1}{i} \\ &= \frac{H_{|S|}}{H_n} c(S) \leq c(S) \end{aligned}$$

## Primal-Dual:

General P-D "schema" (for min problem):

- 1) Write down primal LP relaxation (min), dual LP (max)
- 2) Start with  $x = \vec{0}$  (primal infeasible),  $y = \vec{0}$  (dual feasible)
- 3) Until  $x$  is primal feasible:

- Increase  $y$  until some dual constraint becomes tight  
(maintaining feasibility of  $y$ )

- Select some of the tight dual constraints, increase corresponding primal variables integrally  
(intuition: complementary slackness)

- "Freeze" dual variables in tight dual constraints

Analysis: prove  $c^T x \leq \alpha \cdot b^T y$  for some  $\alpha$

$\Rightarrow$  since  $x, y$  feasible primal/dual solutions,

$$\Rightarrow c(x) \leq \alpha \cdot \text{OPT}$$

$\leq \alpha$

$c^T x$   
+  $\text{OPT}$   
+ primal LP OPT  
= dual LP OPT  
+  $b^T y$

## P-D for Set Cover:

-  $y = \vec{0}$ ,  $I = \emptyset$  ( $x = \vec{0}$ )

- while  $\exists e \in U$  with  $e \notin \bigcup_{S \in I} S$

- Increase  $y_e$  until  $\exists$  some  $S \notin I$  with  $e \in S$  s.t.  $\sum_{e' \in S} y_{e'} = c(S)$

$$\min_{S \notin I, e \in S} (c(S) - \sum_{e' \in S} y_{e'})$$

- Add  $S$  to  $I$  (set  $x_S = 1$ )

- return  $I(x)$

$$\sum_{e \in S} y_e \leq c(S) \quad (\text{dual constraint})$$

Thm: P-D is an  $f$ -approximation ( $f = \max_{e \in U} |\{S \in \mathcal{S} : e \in S\}|$ )

Pf:  $y$  always dual feasible:

induction: - true at beginning

- If constraint for  $S$  becomes tight, all elements in  $S$  covered

$\Rightarrow y_e$  never increased again for any  $e \in S$

$$PD = \sum_{S \in I} c(S) = \sum_{S \in I} \sum_{e \in S} y_e \quad (\text{dual constraint tight } \forall S \in I)$$

$$= \sum_{e \in S} y_e \cdot |\{S \in I : e \in S\}| \quad (\text{switch order of summation})$$

$$\leq \sum_{e \in E} f \cdot y_e$$

(def of  $f$ )

$$= f \sum_{e \in E} y_e$$

$$\leq f \cdot \text{OPT}$$

(weak duality)

## Shortest s-t path:

-  $G = (V, E)$ ,  $c: E \rightarrow \mathbb{R}^+$ ,  $s, t \in V$  (can run Dijkstra)

-  $\mathcal{S} = \{S \subseteq V : s \in S, t \notin S\}$

Primal LP:

$$\min \sum_{e \in E} c(e) x_e$$

$$\text{s.t.} \quad \sum_{e \in \delta(S)} x_e \geq 1 \quad \forall S \in \mathcal{S}$$

$$x_e \geq 0 \quad \forall e \in E$$

Dual LP:

$$\max \sum_{S \in \mathcal{S}} y_S$$

$$\text{s.t.} \quad \sum_{S \in \mathcal{S} : e \in \delta(S)} y_S \leq c(e) \quad \forall e \in E$$

$$y_S \geq 0 \quad \forall S \in \mathcal{S}$$

PD Alg:

-  $y = \vec{0}$ ,  $F = \emptyset$

- while no s-t path in  $(V, F)$  {

- Let  $C$  be connected component of  $(U, F)$  containing  $s$

- Increase  $y_c$  until some  $e \in \delta(C)$  has

$$\sum_{S \in \mathcal{D}: e \in \delta(S)} y_S = c(e)$$

- Add  $e$  to  $F$

}

- Return an  $s$ - $t$  path  $P$  in  $(U, F)$

Fact: this is Dijkstra's Algorithm!

Lemma: Throughout algorithm,  $F$  is a tree containing  $s$

Pf: Induction.

Init:  $F = \emptyset$ . Trivially true

Inductive step:

$S_{ps}$  true at some point.

PO adds  $e \in \delta(C)$  to  $F$

$\Rightarrow F$  still a tree

Lemma: If  $y_S > 0$ , then  $|P \cap \delta(S)| = 1$

Pf:  $S_{ps}$  false:  $y_S > 0$  but  $|P \cap \delta(S)| > 1$

$P'$ : subpath of  $P$  with only first and last endpoints in  $S$

When  $y_S$  increased,  $F$  was a tree spanning  $S$

$\Rightarrow F$  has an  $s-v$  path inside  $S$

$\Rightarrow F \cup P'$  has a cycle

$\Rightarrow \Leftarrow$

Thm: PD finds shortest  $s-t$  path

PF:

$$\sum_{e \in P} c(e) = \sum_{e \in P} \sum_{S: e \in \delta(S)} y_S$$

(every edge added has tight dual constraint)

$$= \sum_{S \in \mathcal{S}} \sum_{e \in P \cap \delta(S)} y_S$$

(switch order of summation)

$$= \sum_{S \in \mathcal{S}} y_S |P \cap \delta(S)|$$

$$= \sum_{S \in \mathcal{S}} y_S$$

(Lemma)

$$\leq \text{OPT}$$

(weak duality)
